
tau is the LEARNER radius, and in this regime the evaluation radius MOVES with it (evaluation tau = learner tau), so each point is a different estimand: this panel is a diagnostic, not the cross-radius comparison. NLHF is passive-trained in every condition of this study and is drawn here as the passive-trained benchmark, never as an active learner. Per-group levels are drawn without intervals: many marginal intervals on one sheet would read as a simultaneous statement, and these intervals are marginal per cell.
